

## CLAIMS

We claim:

- Sue O*
1. An inter-chip communication system for the communication of a plurality of N-bit signal groups between a first logic device and a second logic device that are coupled together through an M-bit wide conductive element, comprising:
    - 4 transmission logic in the first logic device for transmitting any N-bit signal group that changed in value M bits at a time across the M-bit conductive element; and
    - 5 reception logic in the second logic device for receiving the N-bit signal group.
  - 1 2. The inter-chip communication system of claim 1, wherein the transmission logic further comprises:
    - 3 an event detector for detecting a change in value among the N-bit signal groups and providing an event indication identifying the particular signal group that changed in value.
  - 1 2. The inter-chip communication system of claim 1, wherein the transmission logic further comprises:
    - 3 an event detector for each N-bit signal group for detecting a change in value in its associated N-bit signal group and providing an event indication identifying that its N-bit signal group changed in value.
  - 1 2 4. The inter-chip communication system of claim 2, wherein  $N > M$  and the transmission logic further comprises:
    - 3 a packet scheduler for receiving the event indication and dividing the N-bit signal group associated with the event indication into M-bit data groups.
  - 1 2 5. The inter-chip communication system of claim 3, wherein  $N > M$  and the transmission logic further comprises:
    - 3 a packet scheduler for each N-bit signal group for receiving the event indication from the

4 event detector associated with its N-bit signal group and dividing the N-bit signal group into M-  
5 bit data groups.

1  
2  
3  
4 6. The inter-chip communication system of claim 4, wherein the transmission logic further  
comprises:  
scan-out logic for selecting the M-bit data groups for transmission across the M-bit  
conductive element.

1  
2  
3  
4 7. The inter-chip communication system of claim 5, wherein the transmission logic further  
comprises:  
scan-out logic for selecting the M-bit data groups for transmission across the M-bit  
conductive element.

1  
2  
3  
4 8. The inter-chip communication system of claim 1, wherein each N-bit signal group is  
associated with an identifying header, the reception logic further comprising:  
header decode unit for receiving the M-bit data groups and determining which N-bit signal  
group these M-bit data groups belong.

1  
2  
3  
4 9. The inter-chip communication system of claim 5, wherein the packet scheduler is capable  
of receiving, holding, and passing a token.

1  
2 10. The inter-chip communication system of claim 5, wherein the packet scheduler transmits  
its M-bit data groups when it holds a token.

1  
2 11. The inter-chip communication system of claim 10, wherein the packet scheduler holds a  
token, when it receives the token and an event indication.

1  
2 12. The inter-chip communication system of claim 10, wherein the packet scheduler passes a  
token, when it receives the token and no event indication has been received.

1    13. A data transmission communication system for the transmission of a plurality of N-bit  
2 signal groups from a first logic device to a second logic device that are coupled together through  
3 an M-bit wide conductive element, comprising:

4                 an event detector network for detecting a change in value among the N-bit signal groups  
5 and providing an event indication identifying the particular signal group that changed in value;  
6 and

7                 a scheduler for selecting the N-bit signal group that changed in value and scheduling its  
8 transmission.

1    14. The data transmission communication system of claim 13, wherein  $N > M$  the scheduler  
2 divides the N-bit signal group into a plurality of M-bit groups.

1    15. The data transmission communication system of claim 13, wherein the event detector  
2 network includes a plurality of event detectors and each event detector is associated with its own  
3 N-bit signal group.

1    16. The data transmission communication system of claim 15, wherein the event detector for  
2 each N-bit signal group detects a change in value in its associated N-bit signal group and provides  
3 an event indication identifying that its N-bit signal group changed in value.

1    17. The data transmission communication system of claim 15, wherein the scheduler includes  
2 a plurality of packet schedulers and each packet scheduler is associated with its own N-bit signal  
3 group.

1    18. The data transmission communication system of claim 16, wherein the scheduler includes  
2 a plurality of packet schedulers and each packet scheduler is associated with its own N-bit signal  
3 group.

*Sud 1*  
*Sud 2*  
*Sud 3*

1 19. The data transmission communication system of claim 18, wherein the plurality of packet  
2 schedulers decides among themselves which N-bit signal group to transmit.

*Sud 1*  
*Sud 2*  
*Sud 3*

1 20. The data transmission communication system of claim 19, wherein  $N > M$  and each packet  
2 scheduler receives the event indication and divides the N-bit signal group associated with the  
3 event indication into M-bit data groups.

*Sud 1*  
*Sud 2*  
*Sud 3*

1 21. The data transmission communication system of claim 19, wherein the plurality of packet  
2 schedulers passes tokens to each other and depending on which packet scheduler receives an event  
3 indication, each packet scheduler holds the token or passes the token.

*Sud 1*  
*Sud 2*  
*Sud 3*

1 22. The data transmission communication system of claim 19, wherein the packet scheduler  
2 transmits its M-bit data groups when it holds a token.

*Sud 1*  
*Sud 2*  
*Sud 3*

1 23. The data transmission communication system of claim 20, wherein the packet scheduler  
2 transmits its M-bit data groups when it holds a token.

*Sud 1*  
*Sud 2*  
*Sud 3*

1 24. The data transmission communication system of claim 19, wherein the packet scheduler  
2 holds a token when it receives the token and an event indication.

*Sud 1*  
*Sud 2*  
*Sud 3*

1 25. The data transmission communication system of claim 19, wherein the packet scheduler  
2 passes a token, when it receives the token and no event indication has been received.

*Sud 1*  
*Sud 2*  
*Sud 3*

1 26. A method of scheduling the transmission of a packet from a first logic device to a second  
2 logic device across an M-bit wide connection, the packet selected from a plurality of N-bit signal  
3 groups, comprising steps:

4       detecting a change in value among the N-bit signal groups;  
5       selecting the changed N-bit signal group for transmission;  
6       processing the N-bit signal group into a transmission data group; and

7 transmitting the transmission data group across the M-bit wide connection.

1 27. The method of claim 26, wherein  $N > M$  and the step of processing further comprises:  
2 dividing the N-bit signal groups into M-bit data groups, wherein the transmission data  
3 group comprises the M-bit data groups.

1 28. The method of claim 26, wherein the step of selecting further comprises:  
2 identifying the N-bit signal group that experienced the change in value; and  
3 determining when the N-bit signal group should be transmitted.

1 29. The method of claim 27, wherein the step of transmitting includes:  
2 transmitting the transmission data group by transmitting, M bits at a time, each M-bit data  
3 group.

1 30. The method of claim 28, wherein the step of determining includes:  
2 determining whether the identified N-bit signal group currently has a token; and  
3 scheduling the transmission of the identified N-bit signal group if it has the token.
